

Advances in Parenteral Nutrition: Proceedings of an International Symposium held in Bermuda, 16-19th May, 1977

Parenteral nutrition has been one of the most significant therapeutic advances of the past twenty years. Many patients have survived very serious illness only because of intravenous nutrition for either short or very long periods of time. The indications for parenteral nutrition are simple and can be summarised as the inability to ingest necessary nutrients for a significant time during increased metabolic demands. Many problems in the preparation of energy sources and amino acid solutions have been solved so that the time is opportune to review what has been achieved and discuss recent advances and current thinking in the light of future requirements. The next phase in parenteral nutrition will undoubtedly be the provision of regimens designed for specific situations. The needs of the neonate for example are known to differ from adult requirements. The choice of carbohydrate for intravenous use has been a matter of much of glucose both in biochemical and clinical terms discussion. The supremacy now seems well established. The value of intravenous fat is well documented, but the interchange of fat and carbohydrate as calorie sources and the effects of prolonged infusions of fat merit further investigation. The evidence that isotonic amino acids are utilized effectively when given alone due to the availability of endogenous energy sources has led to a greater understanding of the metabolic changes and demands associated with injury and sepsis.
